## Papers in Press

“Papers in Press” includes peer-reviewed, accepted manuscripts of research articles, reviews, and short notes to be published in *Paleontological Research*. They have not yet been copy edited and/or formatted in the publication style of *Paleontological Research*. As soon as they are printed, they will be removed from this website. Please note they can be cited using the year of online publication and the DOI, as follows:

13 **Running head:** Neocete humerus from Miyazaki

14 **Abstract**

15 The Late Palaeogene represents a crucial time in cetacean evolution that witnessed the  
16 origin of modern baleen and toothed whales (Neoceti) from their “archaeocete” ancestors. So  
17 far, this fundamental transition has been discussed mainly in terms of cranial morphology,  
18 whereas descriptions of postcranial material remain rare. Here, we report a small cetacean  
19 humerus from the Nichinan Group (Early Oligocene to Early Miocene), Kushima City,  
20 Miyazaki Prefecture, southern Kyushu, Japan. Our specimen resembles archaeocete humeri  
21 in being proximodistally elongate and in retaining a distinct deltoid ridge, but shares with  
22 neocetes the defining feature of an immobilised elbow joint. It resembles most Oligocene  
23 odontocetes in its small size and in lacking a notch marking the position of the distal  
24 epiphysis, and is furthermore similar to the enigmatic *Microzeuglodon* in having a  
25 transversely compressed shaft. A morphometric analysis based on five linear measurements,  
26 however, fails to cluster our specimen with any other known group of cetaceans, indicating

27 that it is not easily referable to either basal mysticetes or odontocetes. Therefore, we here  
28 classify it as Neoceti *incertae sedis*.

29

30 **Keywords:** Cetacea, Neoceti, Nichinan Group, Humerus, Cenozoic, Morphometric analysis

### 31 **Introduction**

32 The latest Eocene and Oligocene are of major interest to the study of cetacean  
33 evolution, as it is likely during this time that modern whales and dolphins (Neoceti) first  
34 arose from their archaeocete forebears (Fordyce and de Muizon, 2001). Research into the  
35 origin of Neoceti is frequently tied to cranial features reflecting the evolution of baleen and  
36 echolocation, which characterise extant baleen whales (Mysticeti) and toothed whales  
37 (Odontoceti), respectively. However, the archaeocete–neocete transition also resulted in  
38 marked shifts in postcranial morphology. Freed from the need to support their own weight on  
39 land, neocetes lost external hind limbs, and the forelimbs became largely inflexible and  
40 primarily used for steering. Osteologically, the use of the forelimb as a flipper is reflected in a  
41 variety of features, including (1) the immobilisation of the elbow joint; (2) the shortening of  
42 the humerus relative to the radius and ulna; (3) the widening of the distal epiphysis of the  
43 humerus relative to the shaft; (4) the reduction of certain muscle attachment sites; and (5), in  
44 some taxa, the loss of one digit and /or the appearance of hyperphalangy (e.g. Cooper *et al.*,  
45 2007a; Cooper *et al.*, 2007b).

46 Exactly when and in what order these changes occurred remains unclear, as the record  
47 of early neocete limb bones is still extremely patchy. Here, we report a new Late Oligocene  
48 to Early Miocene cetacean humerus from Miyazaki Prefecture, Kyushu, Japan (Figure 1).  
49 The new specimen stands out both for its archaic morphology and its diminutive size, which  
50 puts it among the smallest cetaceans so far described. In addition, depending on its exact age,  
51 it may represent the first record of Cetacea from the Palaeogene of southern Kyushu.

52

## 53 **Material and Methods**

54 We describe and compare the new material (MGF3848) with other cetacean humeri,  
55 following the morphological terminology of Flower (1885). Additionally, to provide a  
56 comparative context, we quantified the shapes of both our specimen and a range of archaic  
57 and modern taxa (Table 1) via a series of five linear measurements (Figure 2) as defined by  
58 Uhen (2004), which we then subjected to Principal Components Analysis in PAST, ver. 3.11  
59 (Harper and Ryan 2001). Except for MGF3848 and the humerus of *Morawanocetus yabukii*  
60 (AMP 01), measurements were based on photographs and published figures, estimating the  
61 length of missing or hidden parts where necessary and feasible. All of the measurements were  
62 chosen so that they could be taken based on the outline of the humerus only. For consistency,  
63 humeri were preferably measured in lateral view, unless the latter was unavailable (Table 1).  
64 For modern taxa lacking a deltoid ridge, deltoid ridge breadth (DRB) was substituted by mid-  
65 distal humeral shaft breadth. Prior to the performing the PCA, we factored out body size by  
66 expressing all of our measurement data as ratios relative to the sum of the five linear  
67 measurements. The results of the PCA therefore reflect variations in shape only.

78 familia *incertae sedis*

79 Figure 3

80 Material.—MGF3848, a left humerus.

81 Locality and horizon.—MGF3848 was collected at Takamatsu Beach ( $31^{\circ} 27' 21.5''$  N,  
82  $131^{\circ} 11' 23.6''$  E, WGS84), located in Kushima City, Miyazaki Prefecture, Japan (Figure  
83 1). The layer that yielded the specimen forms part of the Nichinan Group (Figure 1), a large-  
84 scale olistostrome originally deposited during Early Oligocene to Early Miocene (Sakai *et al.*,  
85 1987). The fossiliferous horizon belongs to the coherent unit of the Nichinan Group and  
86 appears to be located within the Honjo Olistolith of Sakai *et al.* (1987). Earlier work referred  
87 the deposits in the Takamatsu area to the Kushima Formation and dated them to the Middle  
88 Eocene–Early Oligocene (Kato, 1985). However, this subdivision of the sequence appears to  
89 include portions of the chaotic unit of the Nichinan Group, which is in turn derived from the  
90 older Hyuga Group (Sakai *et al.*, 1987) and thus likely to provide unreliable dates.

91 We failed in our attempts to obtain any microfossils, calcareous or otherwise, from  
92 the matrix surrounding the specimen, but note that the lithology (alternating beds of  
93 sandstone and siltstone), invertebrate fauna and paucity of microfossils at the locality  
94 strongly resemble marine sand bar, lagoon and tidal flat deposits exposed in the Toi-Misaki  
95 area, about 15 km to the south east (Sakai, 1988). At Toi-Misaki, those strata have yielded  
96 foraminifera indicative of planktonic foraminiferal zone P21, which at 29.2–26.9 Ma  
97 straddles the Early/Late Oligocene boundary (Anthonissen and Ogg, 2012; Vandenberghe *et*  
98 *al.*, 2012). This estimate may be corroborated by the occurrence of foraminifera correlating  
99 with zones P20 and P21 in a portion of the Honjo Olistolith exposed closer to the fossil  
100 locality, near the mouth of the Honjo river (Sakai *et al.*, 1987: fig. 3). Nevertheless, given the

101 chaotic nature of the Nichinan Group and the absence of direct dating evidence, the actual  
102 age of MGF3848 remains open to question.

103 Description.— MGF3848 is small (132 mm long), gracile and proximodistally elongate, with  
104 fused proximal and distal epiphyses (Table 2; Figure 3). In lateral view, the humeral head is  
105 relatively small, oriented roughly dorsally and does not overhang the posterior margin of the  
106 shaft. The small tuberosity is well developed and nearly as large as the head itself. The great  
107 tuberosity is broken. Immediately distal to the humeral head, the shaft is transversely  
108 compressed and bears a moderately developed deltoid ridge along roughly three quarters of  
109 its anterior margin. The posterior margin of the shaft is weakly concave and, as in extant  
110 cetaceans, confluent with the articular facet of the ulna. By contrast, basilosaurids and a  
111 variety of basal neocetes have a distal epiphysis that is offset from the posterior border of a  
112 shaft by a distinct notch (Figure 4). The distalmost portion of the shaft is about as wide  
113 anteroposteriorly as the distal epiphysis. The radial and ulnar articular facets are relatively  
114 flat and separated by a distinct angle, thus rendering the elbow joint inflexible.

115

116 Morphometric analysis.—The first two principal components (PCs) explain 96% of the total  
117 variance (Figure 5). PC 1 defines a gradient separating basilosaurid archaeocetes (lower  
118 scores) from mysticetes and odontocetes. PC 2 is less well defined, but reasonably separates  
119 archaic mysticetes and odontocetes from their modern relatives (*Pelocetus*, *Balaenoptera*,  
120 and *Physeter*). The morphospaces occupied by archaic mysticetes (lower PC 1 and higher PC  
121 2 scores) and odontocetes (higher PC 1 and lower PC 2 scores) are close, but do not overlap.  
122 Somewhat unexpectedly, MGF3848 is well separated from other archaic neocetes and instead  
123 plots between archaeocetes and modern neocetes, roughly in line with *Fucaia*, *Yamatocetus*  
124 and *Mirocetus* according to PC 1, primarily because of its considerable length (HL) and

125 narrow shaft (DRB and HPD). Nevertheless, MGF3848 does plot within the 95% confidence  
126 ellipse of Odontoceti, but outside that of Mysticeti.

127

## 128 **Discussion**

129 Our morphometric analysis separates archaeocetes from neocetes, with the extant  
130 *Balaenoptera* and *Physeter* forming a distinct cluster with the relatively modern-looking  
131 *Pelocetus*. This grouping is driven by a widening of the distal epiphysis and the reduction or  
132 loss of the deltoid ridge, and reflects a certain degree of convergent evolution of modern  
133 mysticete and odontocete humeri. Archaic Mysticeti and Odontoceti are marginally  
134 separated, with *Mirocetus riabinini* and *Phoberodon arctirostris* plotting closer to  
135 archaeocetes and modern neocetes, respectively, than other Oligocene odontocetes. This  
136 patterns may be indicative of a morphological transition: whereas *M. riabinini*, a basal  
137 odontocete, retains a well-defined deltoid ridge and archaic-looking distal epiphysis (Sanders  
138 and Geisler, 2015), *Phoberodon*, a Miocene squalodontid, has a deltoid ridge that is more  
139 reduced than in other Oligocene neocetes (Cabrera, 1926). It should be noted, however, that  
140 our data on *Phoberodon* are limited to a relatively old drawing (Cabrera, 1926: fig.16), and  
141 that some apparent damage to the anterior surface of its humerus may have led us to  
142 underestimate HPD.

143 MGF3848 is clearly a neocete, based on the immobilisation of the elbow – a feature  
144 that is typical of both mysticetes and odontocetes, but absent in archaeocetes (Uhen, 2004).  
145 Corroboration for this assessment comes from the lack of a notch separating the distal  
146 epiphysis from the posterior margin of the shaft, as seen in crown mysticetes and all but the  
147 most archaic odontocetes (Figure 4). The morphometric analysis also seems to provide some,  
148 albeit weak, support for this assessment, with MGF3848 being slightly closer to the archaic  
149 neocetes *Yamatocetus* and *Mirocetus* than to archaeocetes in terms of its PC 1 score (Fig. 5).

150 On the other hand, MGF3848 also preserves a range of primitive, archaeocete-like features,  
151 including (1) its proximodistal elongation, (2) a well-developed deltoid ridge (relative to  
152 modern Neoceti) and (3) a distal epiphysis that is no wider anteroposteriorly than the humeral  
153 shaft. This preponderance of primitive traits again becomes apparent in the morphometric  
154 analysis, which places MGF3848 between archaeocetes and modern neocetes.

155 In some respects, MGF3848 is more similar to archaic odontocetes and the  
156 enigmatic *Microzeuglodon* – here regarded as a neocete owing to the angular arrangement of  
157 the radial and ulnar facets (see Lydekker, 1892) – than to archaic mysticetes: first, because it  
158 lacks the notch separating the distal epiphysis from the shaft, with the latter being present in  
159 aetiocetids and eomysticetids, but absent in *Microzeuglodon* and all described odontocetes  
160 save *Mirocetus* (Figure 4); secondly, because it specifically resembles *Microzeuglodon* in  
161 having a transversely compressed shaft; and, finally, because of its relatively small size.  
162 Thus, the humeral lengths of both *M. caucasicum* (ca 110 mm) and at least some Oligocene  
163 odontocetes (e.g. *Sulakocetus dagestanicus*, ca 130 cm) are comparable to that of MGF3848  
164 (Lydekker, 1892; Mchedlidze, 1984).

165 By contrast, mysticetes are generally larger: all sufficiently known eomysticetids,  
166 including *Eomysticetus whitmorei*, *Tokarahia kauaeroa* and *Yamatocetus canaliculatus* have  
167 humeri that are twice as long or longer than MGF3848 (Boessenecker and Fordyce, 2015;  
168 Okazaki, 2012; Sanders and Barnes, 2002). Aetiocetids, such as *Fucaia goedertorum* (216  
169 mm) and *Morawanocetus yabukii* (158 mm, T. Ando 2015, pers. comm.), are closer to  
170 MGF3848 in terms of their size but still consistently larger, with their known humeral lengths  
171 exceeding that of MGF3848 by 18% (in case of *M. yabukii*) or more. No limb material has  
172 yet been described for mammalodontids, which are also relatively small-bodied. However,  
173 mammalodontids have so far only been found in Australasia and, possibly, the Mediterranean  
174 (Bianucci *et al.*, 2011; Fitzgerald, 2010). Judging from the size of their skulls, they are

175 probably also larger than MGF3848 and more comparable to medium-sized aetiocetids  
176 (Pyenson and Sponberg, 2011; Tsai and Ando, 2015), although it is important to note that  
177 there are currently no data on the relationship between skull and humerus/limb size in early  
178 neocetes.

179 In line with the above comparisons, the results of the morphometric analysis place  
180 MGF3848 outside the 95% confidence ellipse of Mysticeti, and inside – albeit barely – that of  
181 Odontoceti (Fig. 5). Nevertheless, the analysis also shows that MGF3848 is considerably  
182 more slender (i.e. proximodistally longer with a less developed deltoid ridge) than any other  
183 Oligocene neocete. In addition, MGF3848 specifically differs from *Mirocetus riabinini* and  
184 *Sulakocetus dagestanicus* in having a humeral head that is aligned with the posterior border  
185 of the shaft in lateral view, from *Otekaikea huata* and *Phoberodon arctirostris* in being more  
186 compressed transversely, and from *F. kelloggi*, *O. huata*, *Prosqualodon davidis* and  
187 *Phoberodon arctirostris* in having a better developed (compared to *Phoberodon* and  
188 *Prosqualodon*) or proximodistally longer deltoid ridge (compared to *Ferecetoherium* and  
189 *Otekaikea*). MGF3848 furthermore differs from *F. kelloggi*, *P. davidis* and, to a lesser degree,  
190 *O. huata* in lacking an anteroposteriorly expanded distal epiphysis, and from *O. huata* in  
191 lacking a well-defined fossa for the origins of the infraspinatus muscle (Cabrera, 1926; Flynn,  
192 1948; Tanaka and Fordyce, 2015). Finally, MG3848 differs from *Microzeuglodon*  
193 *caucasicum* in that its small tuberosity that does not rise above the level of the head in  
194 anterior view. Overall, it therefore appears that, at least for the moment, MGF3848 is not  
195 clearly referable to any known neocete taxon.

196

## 197 **Conclusion**

198 MGF3848 is a neocete characterised by a mix of primitive and derived features,  
199 including an inflexible elbow joint and the lack of a posterior notch on the distal epiphysis,

200 but does not present an obvious match with any described early neocete limb material. We  
201 therefore refrain from assigning it to either mysticetes or odontocetes. Its small size is most  
202 consistent with MGF3848 representing an archaic odontocete or, possibly, a stem neocete,  
203 similar to *Microzeuglodon causicum*, but neither of these suggestions is unequivocally  
204 borne out by the results of our morphometric analysis. The apparent separation of MGF3848  
205 from other neocetes may suggest that it represents a novel type of archaic neocete not clearly  
206 assignable to any established family. It is equally possible, however, that its relative isolation  
207 simply reflects a lack of comparative material, and will diminish or disappear with the  
208 publication of additional data on early neocete limb morphology. Future discoveries of  
209 additional archaic neocete limb bones, likely also from the Oligocene, will help to settle this  
210 question.

211

## 212 **Acknowledgements**

213 We would like to thank Toshiya Uchida (Kushima City), who discovered the specimen and  
214 kindly donated it to the Miyazaki Prefectural Museum of Nature and History. We also thank  
215 Takamasa Kawano (Miyazaki City), for guiding us to the locality; Tatsuro Ando (AMP), for  
216 providing measurements of aetiocetid humeri and allowing us to use unpublished material  
217 forming part of the holotype of *Morawanocetus yabukii*; Yoshihiro Tanimura (NMNS), for  
218 searching a matrix sample from the locality for microfossils; Hiroshi Nishi (Tohoku  
219 University Museum) for providing stratigraphic and geochronological information on the  
220 Nichinan Group; Minoru Baba (KMNH) for providing information on specimen numbers;  
221 Tomoyuki Ohashi (KMNH) and Lawrence G. Barnes (LACM) for access to specimens under  
222 their care; and R. Ewan Fordyce and Yoshihiro Tanaka for their constructive reviews, which  
223 greatly improved the manuscript. This work was funded in part by a Japan Society for the  
224 Promotion of Science Postdoctoral Fellowship to FGM.

### 311 **Figure captions**

312 **Figure 1.** Age of the Nichinan Group (A) and locality map of Kushima City, Kyushu, Japan  
313 (B). The star marks the exact locality of MGF3848 on Takamatsu Beach. Stratigraphy after  
314 Sakai et al. (1987), modified according to Vandenberghe et al. (2012).

315 **Figure 2.** Measurements used for the morphometric analysis. Abbreviations: HHD, humeral  
316 head diameter; HPD, humeral proximal diameter; HL, humeral length; DRB, deltoid ridge  
317 breadth; HDB, humeral distal breadth. In neocetes lacking a deltoid ridge, DRB was replaced  
318 with the diameter of the distal humeral shaft. Figure 2

319 **Figure 3.** Photographs of MGF3848. A, medial view; B, anterior view; C, lateral view.

320 **Figure 4.** Comparison of the distal epiphysis of the humerus of various archaic cetaceans.  
321 The dashed lines indicate the contour of the posterior border at the distal epiphysis. A,  
322 MGF3848; B, the basilosaurid archaeocete *Dorudon atrox*; C, the aetiocetid mysticete *Fucaia*  
323 *goedertorum*; D, the eomysticetid mysticete *Yamatocetus canaliculatus*; E, the enigmatic  
324 neocete *Microzeuglodon caucasicum*; F, waipatiid odontocete *Sulakocetus dagestanicus*; and  
325 G, the balaenopteroid mysticete *Pelocetus calvertensis*. Note the absence of a notch

326 separating the distal epiphysis from the posterior border of the shaft in MGF3848,  
327 *Microzeuglodon*, *Sulakocetus* and *Pelocetus*.

328 **Figure 5.** Results of the morphometric analysis. Note the position of MGF3848 between  
329 archaeocetes and modern neocetes. The straight dashed lines represent the projections of the  
330 original variables. 95% confidence ellipses for Odontoceti and Mysticeti are also shown. For  
331 abbreviations, see Figure 2.

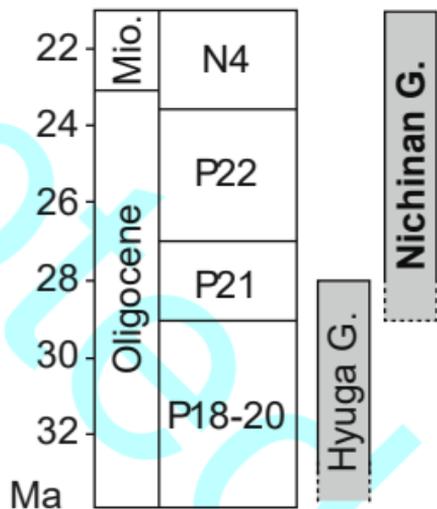

332  
333 **Table captions**

334 **Table 1.** Humerus measurement ratios used for the morphometric analysis. See Fig. 2 for  
335 abbreviations. \*: measurements taken in medial view; #: estimated measurements.

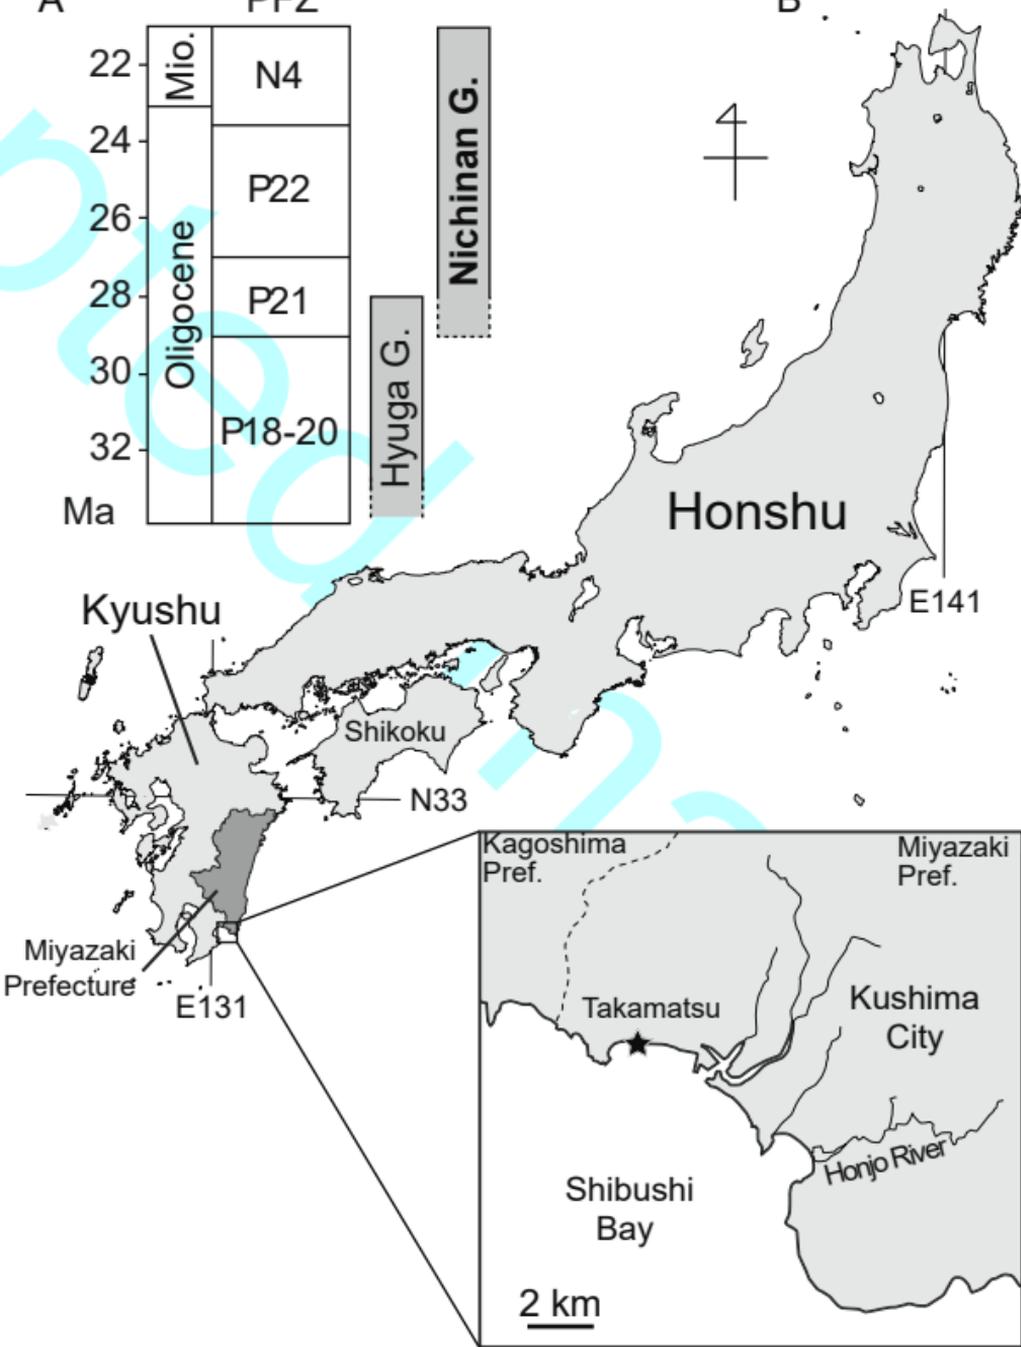

336 **Table 2.** Measurements of MGF3848 (in mm, with error of +/- 0.1 mm). See Fig. 2  
337 for abbreviations; #estimated measurement.
